PHASE PORTRAITS OF A FAMILY OF KOLMOGOROV SYSTEMS DEPENDING ON SIX PARAMETERS

ÉRIKA DIZ-PITA, JAUME LLIBRE, M. VICTORIA OTERO-ESPINAR

Abstract. We consider a general 3-dimensional Lotka-Volterra system with a rational first integral of degree two of the form $H = x^iy^jz^k$. The restriction of this Lotka-Volterra system to each surface $H(x, y, z) = h$ varying $h \in \mathbb{R}$ provide Kolmogorov systems. With the additional assumption that they have a Darboux invariant of the form $x^ly^me^{st}$ they reduce to the Kolmogorov systems

\[
\dot{x} = x(a_0 - \mu(c_1x + c_2z^2 + c_3z)),
\]
\[
\dot{z} = z(c_0 + c_1x + c_2z^2 + c_3z).
\]

We classify the phase portraits in the Poincaré disc of all these Kolmogorov systems which depend on six parameters.

1. Introduction

The Lotka-Volterra systems have been used for modeling many natural phenomena, such as the time evolution of conflicting species in biology [20], chemical reactions, plasma physics [15] or hydrodynamics [6], just as other problems from social science and economics.

These systems, which are polynomial differential equations of degree two, were initially proposed, independently, by Lotka in 1925 and Volterra in 1926, both in the context of competing species. Later on Lotka-Volterra systems were generalized and considered in arbitrary dimension, i.e.

\[
\dot{x}_i = x_i(a_{i0} + \sum_{j=1}^{n} a_{ij}x_j), \quad i = 1, \ldots, n.
\]

Consequently the applications of these systems started to multiply. Moreover Kolmogorov in [13] extended the Lotka-Volterra systems as follows

\[
\dot{x}_i = x_iP_i(x_1, \ldots, x_n), \quad i = 1, \ldots, n,
\]

where $P_i$ are polynomials of degree at most $m$. These kind of systems are now known as Kolmogorov systems. They have in particular all the applications of the Lotka-Volterra systems as for instance in the study of the black holes in cosmology, see [1].

The global qualitative dynamics of the Lotka-Volterra systems in dimension two has been completely studied in [24], where all possible phase portraits on the Poincaré disc have been classified.

There are few results about the global dynamics of the Lotka-Volterra systems in dimension three. Our objective is to study the phase portraits of the 3-dimensional Lotka-Volterra systems
\begin{align}
\dot{x} &= x(a_0 + a_1 x + a_2 y + a_3 z), \\
\dot{y} &= y(b_0 + b_1 x + b_2 y + b_3 z), \\
\dot{z} &= z(c_0 + c_1 x + c_2 y + c_3 z),
\end{align}
(1.1)
which have a rational first integral of degree two of the form \(x^iy^jz^k\). We have used the Darboux theory of integrability to obtain a characterization of these systems. As a result, we have reduced the initial problem to a problem in dimension two, the study of the global dynamics of two families of Kolmogorov systems. In this paper we focus on the first family, which is
\begin{align}
\dot{x} &= x(a_0 + a_1 x + a_2 z^2 + a_3 z), \\
\dot{z} &= z(c_0 + c_1 x + c_2 z^2 + c_3 z),
\end{align}
(1.2)
Kolmogorov systems (1.2) depend on eight parameters, this is a big number to classify all their distinct topological phase portraits. Then we require that Kolmogorov systems (1.2) have a Darboux invariant of the form \(x^iy^jz^k\), then these systems are reduced to study the Kolmogorov systems
\begin{align}
\dot{x} &= x(a_0 - \mu(c_1 x + c_2 z^2 + c_3 z)), \\
\dot{z} &= z(c_0 + c_1 x + c_2 z^2 + c_3 z),
\end{align}
(1.3)
which now depend on six parameters. For these Kolmogorov systems we give the topological classification of all their phase portraits in the Poincaré disc. Roughly speaking the Poincaré disc is the closed unit disc centered at the origin of \(\mathbb{R}^2\). Its interior is identified with \(\mathbb{R}^2\) and the circle of its boundary is identified with the infinity of \(\mathbb{R}^2\). In the plane \(\mathbb{R}^2\) we can go or come from the infinity in as many directions as points have the circle. The polynomial differential systems can be extended to the closed Poincaré disc, i.e. they can be extended to infinity and in this way we can study their dynamics in a neighborhood of infinity. This extension is called the Poincaré compactification, for more details see subsection 2.1. Thus our main result is the following.

**Theorem 1.1.** Kolmogorov systems (1.3) have 102 topologically distinct phase portraits in the Poincaré disc under condition (H1) given in Figure 17.

(H1) \(c_2 \neq 0, a_0 \geq 0, c_1 \geq 0, c_3 \geq 0, a_0 + c_0 \mu \neq 0, a_0 c_1 \mu \neq 0, \mu \neq -1\)

We will see that we can assume condition (H1) because Kolmogorov systems (1.3) can be reduced to satisfy such condition either using symmetries, or eliminating known phase portraits, or eliminating phase portraits with infinitely many finite or infinite singular points. Some topological phase portraits have been classified in the Poincaré disc are; see for instance [4, 13, 17].

In Section 3 using the Darboux theory of integrability we explain the reduction from the Lotka-Volterra system (1.1) to the Kolmogorov systems (1.3). In Section 4 we give some properties of the system obtained. In Section 5 we study the local phase portrait of the finite singular points, and in Section 6 we do the same with...
the infinite singular points, applying the blow-up technique. Finally in Section 7 we prove Theorem 1.1.

2. Preliminaries

2.1. Poincaré compactification. To study the behavior of the trajectories of our polynomial differential systems near infinity we will use the Poincaré compactification. We provide a short summary about this method, more details can be found in [9, Chapter 5].

Let $X = (P(x, y), Q(x, y))$ be a polynomial vector field of degree $d$ defined in $\mathbb{R}^2$. Consider the Poincaré sphere $S^2 = \{y \in \mathbb{R}^3 : y_1^2 + y_2^2 + y_3^2 = 1\}$, and its tangent plane at the point $(0, 0, 1)$ which is identified with $\mathbb{R}^2$.

We consider the central projections $f^+: \mathbb{R}^2 \to S^2$ and $f^-: \mathbb{R}^2 \to S^2$. By definition, $f^+(x)$ is the intersection of the straight line passing through the point $x$ and the origin with the northern hemisphere of $S^2$, and respectively for $f^-(x)$ with the southern hemisphere. The differential $Df^+$ and respectively $Df^-$ send the vector field $X$ into a vector field $\overline{X}$ on $S^2 \setminus S^1$. Note that the points at infinity of $\mathbb{R}^2$ are in bijective correspondence with the points of the equator $S^1$ of $S^2$.

The vector field $\overline{X}$ can be extended analytically to a vector field on $S^2$ multiplying $\overline{X}$ by $y_3^d$. We denote this vector field by $\rho(X)$, and it is called the Poincaré compactification of the vector field $X$ on $\mathbb{R}^2$.

For studying the dynamics of $X$ in the neighborhood of the infinity, we must study the dynamics of $\rho(X)$ near $S^1$. The sphere $S^2$ is a 2-dimensional manifold so we need to know the expressions of the vector field $\rho(X)$ in the local charts $(U_i, \phi_i)$ and $(V_i, \psi_i)$, where $U_i = \{y \in S^2 : y_i > 0\}$, $V_i = \{y \in S^2 : y_i < 0\}$, $\phi_i : U_i \to \mathbb{R}^2$ and $\psi_i : V_i \to \mathbb{R}^2$ for $i = 1, 2, 3$ with $\phi_i(y) = -\psi_i(y) = (y_m/y_i, y_n/y_i)$ for $m < n$ and $m, n \neq i$.

In the local chart $(U_1, \phi_1)$ the expression of $\rho(X)$ is

$$
\dot{u} = v^d \left[-uP\left(\frac{1}{v}, \frac{u}{v}\right) + Q\left(\frac{1}{v}, \frac{u}{v}\right)\right], \quad \dot{v} = -v^{d+1}P\left(\frac{1}{v}, \frac{u}{v}\right),
$$

(2.1)

In the local chart $(U_2, \phi_2)$ the expression of $\rho(X)$ is

$$
\dot{u} = v^d \left[P\left(\frac{1}{v}, \frac{u}{v}\right) - uQ\left(\frac{1}{v}, \frac{u}{v}\right)\right], \quad \dot{v} = -v^{d+1}P\left(\frac{1}{v}, \frac{u}{v}\right),
$$

(2.2)

and in the local chart $(U_3, \phi_3)$ the expression of $\rho(X)$ is

$$
\dot{u} = P(u, v), \quad \dot{v} = Q(u, v).
$$

(2.3)

In the charts $(V_i, \psi_i)$, with $i = 1, 2, 3$, the expression for $\rho(X)$ is the same as in the charts $(U_i, \phi_i)$ multiplied by $(-1)^{d-1}$.

The equator $S^1$ is invariant by the vector field $\rho(X)$ and all the singular points of $\rho(X)$ which lie in this equator are called the infinite singular points of $X$. If $y \in S^1$ is an infinite singular point, then $-y$ is also an infinite singular point and they have the same (respectively opposite) stability if the degree of vector field is odd (respectively even).

The image of the closed northern hemisphere of $S^2$ onto the plane $y_3 = 0$ under the orthogonal projection $\pi$ is called the Poincaré disc $D^2$. Since the orbits of $\rho(X)$ on $S^2$ are symmetric with respect to the origin of $\mathbb{R}^3$, we only need to consider the flow of $\rho(X)$ in the closed northern hemisphere, and we can project the phase portrait of $\rho(X)$ on the northern hemisphere onto the Poincaré disc. We shall present the phase portraits of the polynomial differential systems (1.3) in the Poincaré disc.
2.2. **Topological equivalence between two polynomial vector fields.** Two polynomial vector fields $X_1$ and $X_2$ on $\mathbb{R}^2$ are **topologically equivalent** if there exists a homeomorphism on the Poincaré disc which preserves the infinity $S^1$ and sends the trajectories of the flow of $\pi(\rho(X_1))$ to the trajectories of the flow of $\pi(\rho(X_2))$, preserving or reversing the orientation of all the orbits.

A **separatrix** of the Poincaré compactification $\pi(\rho(X))$ is an orbit at the infinity $S^1$, or a finite singular point, or a limit cycle, or an orbit on the boundary of a hyperbolic sector at a finite or an infinite singular point. The set of all separatrices of $\pi(\rho(X))$ is closed and we denote it by $\Sigma_X$.

An open connected component of $D^2 \setminus \Sigma_X$ is a **canonical region** of $\pi(\rho(X))$. The **separatrix configuration** of $\pi(\rho(X))$ is the union of an orbit of each canonical region with the set $\Sigma_X$, and it is denoted by $\Sigma_X'$. We denote by $S$ (respectively $R$) the number of separatrices (respectively canonical regions) of a vector field $\pi(\rho(X))$.

We say that two separatrix configurations $\Sigma_X'$ and $\Sigma_Y'$ are **topologically equivalent** if there is a homeomorphism $h : D^2 \to D^2$ such that $h(\Sigma_X') = \Sigma_Y'$.

The following theorem of Markus [21], Neumann [22] and Peixoto [23] allows us to investigate only the separatrix configuration of a polynomial differential system in order to determine its phase portrait in the Poincaré disc.

**Theorem 2.1.** The phase portraits in the Poincaré disc of two compactified polynomial vector fields $\pi(\rho(X_1))$ and $\pi(\rho(X_2))$ with finitely many separatrices are topologically equivalent if and only if their separatrix configurations $\Sigma_X'$ and $\Sigma_Y'$ are topologically equivalent.

2.3. **Blow-up technique.** There exist classification theorems for hyperbolic and semi-hyperbolic singular points, and also for nilpotent singular points which can be found in [9, Chapter 2]. The centers are more difficult to study, see for instance [9, Chapter 4]. Whereas to study a singular point for which the Jacobian matrix is identically zero, the only possibility is studying each singular point case by case. The main technique to perform the desingularization of a linearly zero singular point is the blow-up technique. We give a short summary about this method, more details can be found in [2].

Roughly speaking the idea behind the blow up technique is to explode, through a change of variables that is not a diffeomorphism, the singularity to a line. Then, for studying the original singular point, one studies the new singular points that appear on this line, and this is simpler. If some of these new singular points are linearly zero, the process is repeated. Dumortier proved that this iterative process of desingularization is finite, see [8].

Consider a real planar polynomial differential system

\[
\begin{align*}
\dot{x} &= P(x, y) = P_m(x, y) + \ldots, \\
\dot{y} &= Q(x, y) = Q_m(x, y) + \ldots,
\end{align*}
\]

where $P$ and $Q$ are coprime polynomials, $P_m$ and $Q_m$ are homogeneous polynomials of degree $m \in \mathbb{N}$ and the dots mean higher order terms in $x$ and $y$. Note that we are assuming that the origin is a singular point because $m > 0$. We define the **characteristic polynomial** of (2.4) as

\[
F(x, y) := xQ_m(x, y) - yP_m(x, y),
\]

and we say that the origin is a **nondicritical** singular point if $F \neq 0$ and a **dicritical** singular point if $F \equiv 0$. In this last case $P_m = xW_{m-1}$ and $Q_m = yW_{m-1}$, where
$W_{m-1} \neq 0$ is a homogeneous polynomial of degree $m-1$. If $y - vx$ is a factor of $W_{m-1}$ and $v = \tan \theta^*$, $\theta^* \in [0, 2\pi)$, then $\theta^*$ is a singular direction.

The homogeneous directional blow up in the vertical direction is the mapping $(x, y) \rightarrow (x, z) = (x, y/x)$, where $z$ is a new variable. This map transforms the origin of (2.4) into the line $x = 0$, which is called the exceptional divisor. The expression of system (2.4) after the blow up in the vertical direction is

$$
\dot{x} = P(x, xz), \quad \dot{z} = \frac{Q(x, xz) - zP(x, xz)}{x},
$$

that is always well-defined since we are assuming that the origin is a singularity. After the blow up, we cancel an appearing common factor $x^{m-1}$ ($x^m$ if $F \equiv 0$).

Moreover, the mapping swaps the second and the third quadrants in the vertical directional blow up. [2, Propositions 2.1 and 2.2] provide the relationship between the original singular point of system (2.4) and the new singularities of system (2.6).

For additional details see [3].

Finally, to study the behavior of the solutions around the origin of system (2.4), it is necessary to study the singular points of system (2.6) on the exceptional divisor. They correspond to either characteristic directions in the nondicritical case, or singular directions in the dicritical case. It may happen that some of these singular points are linearly zero, in which case we have to repeat the process. As we said before, it is proved in [8] that this chain of blow ups is finite.

2.4. Indices of planar singular points. Given an isolated singularity $q$ of a vector field $X$, defined on an open subset of $\mathbb{R}^2$ or $\mathbb{S}^2$, we define the index of $q$ by means of the Poincaré Index Formula. We assume that $q$ has the finite sectorial decomposition property. Let $e$, $h$ and $p$ denote the number of elliptic, hyperbolic and parabolic sectors of $q$, respectively, and suppose that $e + h + p > 0$. Then the index of $q$ is $i_q = 1 + (e - h)/2$, and it is always an integer.

We recall that the Poincaré compactification of a vector field in $\mathbb{R}^2$ introduced in Subsection 2.1 is a tangent vector field on the sphere $\mathbb{S}^2$, so the next result will be very useful in our study.

**Theorem 2.2** (Poincaré-Hopf Theorem). For every tangent vector field on $\mathbb{S}^2$ with a finite number of singular points, the sum of their indices is 2.

2.5. Invariants and Application of the Darboux Theory. The Darboux Theory of Integrability provides a link between the integrability of polynomial vector fields and the number of invariant algebraic curves that they have. The basic results on dimension two can be found in Chapter 8 of [9], and these results have been extended to $\mathbb{R}^n$ and $\mathbb{C}^n$ in [16, 18, 19].

We consider a real polynomial differential system in dimension three, that is a system of the form

$$
\frac{dx}{dt} = \dot{x} = P(x, y, z), \\
\frac{dy}{dt} = \dot{y} = Q(x, y, z), \\
\frac{dz}{dt} = \dot{z} = R(x, y, z),
$$

(2.7)

where $P, Q$ and $R$ are polynomials in the variables $x, y$ and $z$. We denote by $m = \max\{\deg P, \deg Q, \deg R\}$ the degree of the polynomial system, and we always assume that the polynomials $P, Q$ and $R$ are relatively prime in the ring of the real polynomials in the variables $x, y$ and $z$. 

Theorem 2.3 (Darboux Integrability Theorem). Suppose that a polynomial system \([2.7]\) of degree \(m\) admits \(p\) irreducible invariant algebraic surfaces \(f_i = 0\) with cofactors \(K_i\) for \(i = 1, \ldots, p\). Then the next statements hold.

(a) There exist \(\lambda_i \in \mathbb{C}\) not all zero such that \(\sum_{i=1}^{p} \lambda_i K_i = 0\) if and only if the function \(f_1^{\lambda_1} \cdots f_p^{\lambda_p}\) is a first integral of system \([2.7]\).

(b) There exist \(\lambda_i \in \mathbb{C}\) not all zero such that \(\sum_{i=1}^{p} \lambda_i K_i = -s\) for some \(s \in \mathbb{R}\) if and only if the function \(f_1^{\lambda_1} \cdots f_p^{\lambda_p} \exp(st)\) is a Darboux invariant of system \([2.7]\).

3. Reduction of the Lotka-Volterra systems in \(\mathbb{R}^3\) to the Kolmogorov systems in \(\mathbb{R}^2\)

As we said our objective is to study the global dynamics of the Lotka-Volterra systems \([1.1]\) in dimension three, which have a rational first integral of degree two of the form \(x^i y^j z^k\). The Darboux theory of integrability allow us to obtain a characterization of these systems.

We consider the irreducible invariant algebraic surfaces \(f_1(x, y, z) = x = 0, f_2(x, y, z) = y = 0\) and \(f_3(x, y, z) = z = 0\) of system \([1.1]\), with cofactors \(K_1\), \(K_2\) and \(K_3\), respectively. As \(K_i\) is the cofactor of \(f_i\) we have that

\[X f_i = P \frac{\partial f_i}{\partial x} + Q \frac{\partial f_i}{\partial y} + R \frac{\partial f_i}{\partial z} = K_i f_i.\]

Then for the invariant algebraic surfaces considered we obtain the cofactors \(K_1 = a_0 + a_1 x + a_2 y + a_3 z\), \(K_2 = b_0 + b_1 x + b_2 y + b_3 z\), and \(K_3 = c_0 + c_1 x + c_2 y + c_3 z\), respectively.

Applying Theorem 2.3 since we assume that \(x^{\lambda_1} y^{\lambda_2} z^{\lambda_3}\) is a first integral of system \([1.1]\), we obtain that there exist \(\lambda_i \in \mathbb{C}\), with \(i \in \{1, 2, 3\}\), not all zero, such that \(\sum_{i=1}^{3} \lambda_i K_i = 0\). Apart from the trivial solution \(\{\lambda_1 = 0, \lambda_2 = 0, \lambda_3 = 0\}\), there are the following three solutions of this equation:

\[S_1 = \{c_0 = 0, c_1 = 0, c_2 = 0, c_3 = 0, a_2 = 0, \lambda_1 = 0\},\]

\[S_2 = \{b_0 = -\frac{c_0 \lambda_3}{\lambda_2}, b_1 = -\frac{c_1 \lambda_3}{\lambda_2}, b_2 = -\frac{c_2 \lambda_3}{\lambda_2}, b_3 = -\frac{c_3 \lambda_3}{\lambda_2}, a_1 = 0\},\]

\[S_3 = \{a_0 = \frac{-b_0 \lambda_2 - c_0 \lambda_3}{\lambda_1}, a_1 = \frac{-b_1 \lambda_2 - c_1 \lambda_3}{\lambda_1}, a_2 = \frac{-b_2 \lambda_2 - c_2 \lambda_3}{\lambda_1}, a_3 = \frac{-b_3 \lambda_2 - c_3 \lambda_3}{\lambda_1}\},\]

which give rise to three families of Lotka-Volterra polynomial differential systems of degree two in \(\mathbb{R}^3\), with a first integral of the form \(x^{\lambda_1} y^{\lambda_2} z^{\lambda_3}\).

If we consider the family given by solution \(S_1\), as the parameters \(c_i\), \(i = 0, \ldots, 3\), are zero, we have that \(\dot{z} = 0\) and the Lotka-Volterra system is reduced to:

\[\begin{align*}
\dot{x} &= x(a_0 + a_1 x + a_2 y + a_3 z), \\
\dot{y} &= y(b_0 + b_1 x + b_2 y + b_3 z), \\
\dot{z} &= 0.
\end{align*}\]

As \(\dot{z} = 0\), \(z\) is constant and this system has \(H = z\) as a first integral. Note that if we consider the first integral \(H = x^{\lambda_1} y^{\lambda_2} z^{\lambda_3}\), and apply the conditions given by \(S_1\), it is \(\lambda_1 = \lambda_2 = 0\), we obtain \(H = z^{\lambda_3}\), with \(\lambda_3 = 2\) for getting the degree two, but in this case we will consider the simplest first integral. In each invariant plane with \(z\)
constant, we have a Lotka-Volterra polynomial differential system in \( \mathbb{R}^2 \). The phase portrait of these systems has been studied in [24], so we are not going to deal with this case.

In this article we study the family given by the solution \( S_2 \). This solution provides the values of parameters \( b_i \) as a function of the parameters \( \lambda_2, \lambda_3 \) and \( c_i \), with \( i = 0, \ldots, 3 \), so we can replace them in the expression of \( \dot{y} \) obtaining

\[
\dot{y} = y \left( - \frac{c_0 \lambda_3}{\lambda_2} - \frac{c_1 \lambda_3}{\lambda_2} x - \frac{c_2 \lambda_3}{\lambda_2} y - \frac{c_3 \lambda_3}{\lambda_2} z \right).
\]

If we denote \( \lambda = -\lambda_3/\lambda_2 \), then the original Lotka-Volterra system becomes

\[
\dot{x} = x(a_0 + a_1 x + a_2 y + a_3 z), \\
\dot{y} = \lambda y(c_0 + c_1 x + c_2 y + c_3 z), \\
\dot{z} = z(c_0 + c_1 x + c_2 y + c_3 z).
\]

Given that \( \lambda_1 = 0 \), the first integral \( H = x^{\lambda_1} y^{\lambda_2} z^{\lambda_3} \) is reduced to \( H = y^{\lambda_2} z^{\lambda_3} \), but if this is a first integral, also \( H = (y^{\lambda_2} z^{\lambda_3})^{-1/\lambda_2} \) is a first integral. If we want \( H \) to be rational of degree two, we must take \( \lambda = 2 \). In each level \( H = 1/h \), with \( h \neq 0 \), we will have \( 1/h = z^2/y \), so \( y = h z^2 \) and then, for each \( h \), the initial Lotka-Volterra system on dimension three reduces to the system on dimension two

\[
\dot{x} = x(a_0 + a_1 x + a_2 h z^2 + a_3 z), \\
\dot{z} = z(c_0 + c_1 x + c_2 h z^2 + c_3 z).
\]

We must study the phase portrait of the systems of this family, but it is equivalent to study the phase portraits of the family of Kolmogorov systems in dimension two

\[
\dot{x} = x(a_0 + a_1 x + a_2 z^2 + a_3 z), \\
\dot{z} = z(c_0 + c_1 x + c_2 z^2 + c_3 z).
\] (3.1)

In the particular cases in which \( H \) is zero or infinity, the differential system on dimension three is reduced to a Lotka-Volterra system on dimension two, having in each case \( z = 0 \) and \( y = 0 \), respectively. We recall that these systems had already been studied in [24].

Systems (3.1) depend on eight parameters and the classification of all their distinct topological phase portraits is huge. For this reason we study the subclass of them having a Darboux invariant of the form \( x^{\lambda_1} z^{\lambda_2} e^{st} \). By statement (b) of Theorem 2.3 the expression \( \lambda_1 K_x + \lambda_2 K_z + s \) must be zero, where \( K_x \) and \( K_y \) are the cofactors of the invariant planes \( x = 0 \) and \( z = 0 \), respectively. Note that \( s \) and \( \lambda_1^2 + \lambda_2^2 \) cannot be zero. We obtain the cofactors \( K_x = a_0 + a_1 x + a_2 z^2 + a_4 z \) and \( K_z = c_0 + c_1 x + c_2 z^2 + c_3 z \) and then, solving the equation \( \lambda_1 K_x + \lambda_2 K_z + s = 0 \), we obtain the following two non-trivial solutions

\[
S_1 = \{ s = -a_0 \lambda_1 - c_0 \lambda_2, a_1 = -\frac{c_1 \lambda_2}{\lambda_1}, a_2 = -\frac{c_2 \lambda_2}{\lambda_1}, a_3 = -\frac{c_3 \lambda_2}{\lambda_1} \}, \\
S_2 = \{ s = -c_0 \lambda_2, c_1 = 0, c_2 = 0, c_3 = 0, \lambda_1 = 0 \}.
\]

So we have two subsystems from the initial system (3.1). According to the conditions given by solution \( S_1 \) the first subsystem is

\[
\dot{x} = x \left( a_0 - \frac{c_1 \lambda_2}{\lambda_1} x - \frac{c_2 \lambda_2}{\lambda_1} z^2 - \frac{c_3 \lambda_2}{\lambda_1} z \right).
\]
\[ \dot{z} = z(c_0 + c_1 x + c_2 z^2 + c_3 z). \]

If we denote \( \lambda_2/\lambda_1 = \mu \) and \( \lambda_1 = \lambda \), then this subsystem becomes
\[
\begin{align*}
\dot{x} &= x\left(a_0 - \mu(c_1 x + c_2 z^2 + c_3 z)\right), \\
\dot{z} &= z\left(c_0 + c_1 x + c_2 z^2 + c_3 z\right),
\end{align*}
\]
and its Darboux invariant is \( x^\lambda z^{\lambda \mu} e^{-t\lambda(a_0 + c_0 \mu)}. \) But if this is a Daboux invariant, also it is \( xz^\mu e^{-t(a_0 + c_0 \mu)}. \) Note that in order that we have a Darboux invariant \( a_0 + c_0 \mu \) cannot be zero.

If we consider now the solution \( \tilde{S}_2 \) we obtain the subsystem
\[
\begin{align*}
\dot{x} &= x\left(a_0 + a_1 x + a_2 z^2 + a_3 z\right), \\
\dot{z} &= c_0 z,
\end{align*}
\]
which is equivalent to the previous one, taking \( \mu = 0 \) and interchanging the variables \( x \) and \( z \), so it is sufficient to study the Kolmogorov systems \((3.2)\) depending on six parameters.

4. Properties of system \((1.3)\)

In this section we state some results that will be used on the classification to reduce the number of phase portraits appearing. Note that if \( c_2 = 0 \), then the system \((1.3)\) is a Lotka-Volterra system in dimension 2. A global topological classification of these systems has been completed in \([24]\), so we limit our study to the case \( c_2 \neq 0 \).

We recall that for obtaining system \((1.3)\) we have supposed that system \((3.1)\) has the Darboux invariant \( I = xz^\mu e^{-t(a_0 + c_0 \mu)} \), so it is required that \( a_0 + c_0 \mu \neq 0 \).

**Proposition 4.1.** Consider system \((1.3)\) and suppose that \( (\dot{x}(t), \dot{z}(t)) \) is a solution of this system. If we change \( c_1 \) by \( -c_1 \) (respectively \( c_3 \) by \( -c_3 \)), then \( (\dot{x}(t), \dot{z}(t)) \) (respectively \( (-\dot{x}(t), -\dot{z}(t)) \)) is the solution of the obtained system.

**Remark 4.2.** By Proposition 4.1 we can limit our study to Kolmogorov systems \((1.3)\) with \( c_1 \) and \( c_3 \) non-negatives. In the cases with these parameters negatives, we will obtain phase portraits symmetric to the ones obtained in the positive cases, with respect to the \( z \)-axis when we change the sign of \( c_1 \), and with respect to the \( x \)-axis when we change the sign of \( c_3 \).

**Corollary 4.3.** Consider system \((1.3)\) and suppose \( (\dot{x}(t), \dot{z}(t)) \) is a solution. If \( c_1 = 0 \) (respectively \( c_3 = 0 \)), then \( (-\dot{x}(t), \dot{z}(t)) \) (respectively \( (\dot{x}(t), -\dot{z}(t)) \)) is also a solution.

**Remark 4.4.** Corollary 4.3 simplifies the study of the cases with \( c_1 = 0 \) or \( c_3 = 0 \), because it proves that the phase portraits have to be symmetric with respect to the \( z \)-axis and \( x \)-axis respectively, and this fact will be useful in obtaining the global phase portraits from the local results.

**Proposition 4.5.** Let \( (\dot{x}(t), \dot{z}(t)) \) be a solution of system \((1.3)\). In the next cases we obtain another system with solution \( (-\dot{x}(-t), -\dot{z}(-t)) \).

1. If \( a_0 \), \( c_0 \) and \( c_2 \) are not zero, and we change the sign of all of them.
2. If \( a_0 = 0 \) and we change the sign of \( c_0 \) and \( c_2 \), which are not zero.
3. If \( c_0 = 0 \) and we change the sign of \( a_0 \) and \( c_2 \), which are not zero.
Remark 4.6. To classify all the phase portraits of the Kolmogorov systems (1.3), according to the previous results, it is sufficient to consider \( a_0 \geq 0 \). And when \( a_0 = 0 \) we will consider also \( c_0 > 0 \).

Remark 4.7. In short, according to the previous results and considerations, from now on it will be sufficient to study the Kolmogorov systems (1.3) with the their parameters satisfying

\[(H2) \quad c_2 \neq 0, \quad a_0 \geq 0, \quad c_1 \geq 0, \quad c_3 \geq 0, \quad a_0 + c_0 \mu \neq 0.\]

Theorem 4.8. For system (1.3) the next statements hold.

1. If \( c_1 \neq 0 \), then on any straight line \( z = c t e \neq 0 \), there exists only one contact point.

2. If \( c_1 = 0 \), then there exist two invariant straight lines \( z = (\sqrt{c_3^2 - 4c_0c_2} - c_3)/(2c_2) \) and \( z = -(\sqrt{c_3^2 - 4c_0c_2} + c_3)/(2c_2) \) if \( c_3^2 > 4c_0c_2 \), and one invariant straight line \( z = -c_3/(2c_2) \) if \( c_3^2 = 4c_0c_2 \). There are no contact points on any other straight line \( z = c t e \neq 0 \).

Proof. First we suppose \( c_1 \neq 0 \) and consider a straight line \( z = z_0 \neq 0 \). Then the contact points on this straight line are those on which \( \dot{z} = 0 \) and, as \( z_0 \neq 0 \), the only possible contact point is the one that satisfies \( c_0 + c_1 x + c_2 z_0^2 + c_3 z_0 = 0 \), i.e. the point such that its first coordinate is \( x = -(c_2 z_0^2 + c_3 z_0 + c_0)/c_1 \).

We consider now the case with \( c_1 = 0 \). Then looking for the points on the straight line \( z = z_0 \neq 0 \) satisfying \( \dot{z} = 0 \), we obtain that they must verify the condition \( c_0 + c_2 z_0^2 + c_3 z_0 = 0 \), and solving this equation we obtain that either there are no contact points, or a full straight line of contact points, or two straight line of contact points, depending on the solutions \( z_0 \) of that equation. \( \square \)

5. Study of local finite singular points

System (1.3) has the following finite singularities:

- \( P_0 = (0, 0) \),
- \( P_1 = (0, \frac{R_2 - a_0}{2c_2}) \) and \( P_2 = (0, \frac{R_2 + a_0}{2c_2}) \) if \( c_3^2 > 4c_0c_2 \),
- \( P_3 = (0, \frac{-a_0}{2c_2}) \) if \( c_3^2 = 4c_0c_2 \),
- \( P_4 = (\frac{a_0}{c_1 \mu}, 0) \) if \( c_1 \mu \neq 0 \).

We use the notation \( R_2 = \sqrt{c_3^2 - 4c_0c_2} \) in order to simplify the expressions which will appear. Moreover if \( a_0 = 0 \) and \( c_1 \mu = 0 \), all the points on the \( z \)-axis are singular points, and the system can be reduced to a Lotka-Volterra system in dimension 2. Therefore from now on we will consider the hypothesis

\[(H3) \quad c_2 \neq 0, \quad a_0 \geq 0, \quad c_1 \geq 0, \quad c_3 \geq 0, \quad a_0 + c_0 \mu \neq 0, \quad a_0^2 + (c_1 \mu)^2 \neq 0.\]

Under this assumption there are 6 different cases according to the finite singular points existing for system (1.3), which are given in Table 1. Then we study the possible local phase portraits in each one of the finite singular points under the hypothesis (H3).

The origin is always an isolated singular point for system (1.3), and we have the next classification for its phase portraits: if \( a_0c_0 \neq 0 \) the singularity is hyperbolic and two cases are possible, the origin is a saddle point if \( c_3 < 0 \), and it is an unstable node if \( c_3 > 0 \). If \( a_0 \neq 0 \) and \( c_0 = 0 \) the singularity is semi-hyperbolic and it has two possibilities: if \( c_3 \neq 0 \) then the origin is a saddle-node, if \( c_3 = 0 \) and \( c_2 < 0 \) it
is a topological saddle, and if $c_3 = 0$ and $c_2 > 0$ it is a topological unstable node. Finally if $a_0 = 0$ the origin is a semi-hyperbolic saddle-node.

When $P_1$ is a singular point of system (1.3), it can present different phase portraits. If $c_0 \neq 0$ then $P_1$ is hyperbolic and it can present the following phase portraits: if $c_2(a_0 + c_0\mu)(R_c - c_3) < 0$ then $P_1$ is a saddle, if $a_0 + c_0\mu < 0$ and $c_2(R_c - c_3) < 0$ it is a stable node, and finally if $a_0 + c_0\mu > 0$ and $c_2(R_c - c_3) > 0$ it is an unstable node. The singular point $P_1$ collides with the origin if $c_1 = 0$.

When $P_2$ is a singular point of system (1.3), it can present three different phase portraits: if $c_2(a_0 + c_0\mu) < 0$ then $P_2$ is a saddle, if $a_0 + c_0\mu < 0$ and $c_2 < 0$ then it is a stable node, and if $a_0 + c_0\mu > 0$ and $c_2 > 0$ it is an unstable node.

When $P_3$ is a singularity of system (1.3) it is a semi-hyperbolic saddle-node if $c_3 \neq 0$, and it collides with the origin if $c_3 = 0$.

When $P_4$ is a singularity of system (1.3) it is hyperbolic if $a_0 \neq 0$ and can present two different phase portraits: if $(a_0 + c_0\mu)\mu > 0$ then $P_4$ is a saddle, and if $\mu(a_0 + c_0\mu) < 0$ it is an stable node. If $a_0 = 0$ the singularity $P_4$ collides with the origin.

**Lemma 5.1.** Under hypothesis (H3) there are 50 different cases according to the local phase portrait of the finite singular points of system (1.3), which are given in Tables 2 and 3.

**Proof.** We have to analyze cases 1 to 6 in Table 1 and determine the local phase portraits of the singular points existing in each one of them, according to their individual classification. We start with the first one, in which the conditions, $c_2^3 > 4c_0c_2$ and $c_1\mu \neq 0$ hold. The singular points are $P_0$, $P_1$, $P_2$ and $P_4$. We shall consider three subcases: $a_0 = 0$, $c_0 = 0$ and $a_0c_0 \neq 0$.

Consider case $c_0 = 0$ in which the origin is a saddle-node and $P_1$ collides with the origin. Since $c_0 = 0$ and $a_0 > 0$, the singular point $P_2$ is a saddle if $c_2 < 0$, and an unstable node if $c_2 > 0$. In these two cases $P_1$ can be either a saddle if $\mu > 0$, or a stable node if $\mu < 0$. This leads to cases 1.1 to 1.4 in Table 2.

We continue with the case $a_0 = 0$ in which $P_0$ is again a saddle-node, but in this case it coincides with $P_4$. Suppose that $P_1$ is an unstable node, then we have $c_0\mu > 0$ and $c_2(R_c - c_3) > 0$. By Remark 4.6 we will only consider the case $c_0 > 0$. Then if $c_2 > 0$ and $R_c - c_3 > 0$ taking into account the expression of $R_c$ and squaring both terms, we obtain that $c_2^3 - 4c_0c_2 > c_3^2$, so $c_0c_2 < 0$, which leads to a contradiction. The same occurs if we suppose $c_2 < 0$. Therefore $P_3$ cannot be an unstable node. If $P_1$ is a saddle, then $P_2$ can be a saddle or an unstable node, but not a stable node, which is only possible if $c_0 < 0$, by an analogous reasoning.

</table>
to the previous one. If $P_{1}$ is a stable node then $c_{0}\mu < 0$, so $P_{2}$ can be a saddle or stable node, but not an unstable node because it requires that $c_{0}\mu > 0$. This leads to cases 1.5 to 1.8.

The last case is $a_{0}c_{0} \neq 0$ in which the origin is a hyperbolic singular point. We start when $P_{0}$ is a saddle, then $c_{0} < 0$. First we consider that $P_{1}$ is also a saddle, and so $c_{2}(a_{0} + c_{0}\mu)(R_{c} - c_{3}) < 0$. If $P_{2}$ is a saddle then $c_{2}(a_{0} + c_{0}\mu) < 0$, and we obtain $R_{c} - c_{3} > 0$. From this we deduce like in previous cases that $c_{0}c_{2} < 0$, but we are supposing $c_{0} < 0$ and so $c_{2} > 0$ and $a_{0} + c_{0}\mu < 0$. From the last inequality $a_{0} < -c_{0}\mu$, and so $\mu$ has to be positive. In short $\mu(a_{0} + c_{0}\mu) < 0$, and consequently $P_{4}$ can only be a stable node. If $P_{0}$ and $P_{1}$ are saddles, but $P_{2}$ is a stable node, reasoning in an analogous way we obtain that $P_{4}$ is again a stable node. This leads to cases 1.9 and 1.10. Note that if $P_{0}$ and $P_{1}$ are saddles it is impossible for $P_{2}$ to be an unstable node. In that case we would have that $c_{0} < 0$, $c_{2} > 0$, $a_{0} + c_{0}\mu > 0$ and $R_{c} - c_{3} < 0$. From this last inequality we obtain that $c_{0}c_{2} > 0$, which is a contradiction. We consider now the cases where $P_{0}$ is a saddle and $P_{1}$ an unstable node, in which the conditions $c_{0} < 0$, $a_{0} + c_{0}\mu > 0$ and $c_{2}(R_{c} - c_{3}) < 0$ hold. It is obvious that $P_{2}$ cannot be a stable node because it requires that $a_{0} + c_{0}\mu < 0$, so $P_{2}$ is a saddle if $c_{2} < 0$ and an unstable node if $c_{2} > 0$. In both cases $P_{4}$ can be either a saddle if $\mu > 0$, or a stable node if $\mu < 0$. This leads to cases 1.11 to 1.14. Note that the case with $P_{3}$ a saddle and $P_{1}$ a stable node is not possible, because we would have $c_{0} < 0$, $a_{0} + c_{0}\mu < 0$ and $c_{2}(R_{c} - c_{3}) < 0$. If $c_{2} > 0$ then $R_{c} - c_{3} < 0$, whence we deduce $c_{0}c_{2} > 0$ and get a contradiction. The same argument is valid if $c_{2} < 0$. With analogous reasoning as in the case where $P_{0}$ is an unstable node we obtain the subcases 1.15 to 1.20.

Now we study case 2 of Table 1 in which $c_{1}^{2} > 4c_{0}c_{2}$, $c_{1}\mu = 0$, and $a_{0} \neq 0$. We shall consider three cases: $c_{0} < 0$, $c_{0} > 0$, and $c_{0} = 0$.

We start with case $c_{0} < 0$ in which $P_{0}$ is a saddle. If $P_{1}$ is a saddle, then $P_{2}$ can be a saddle or a stable node. If $P_{2}$ is an unstable node, then we have the conditions $c_{2}(a_{0} + c_{0}\mu)(R_{c} - c_{3}) < 0$, $c_{2} > 0$, and $a_{0} + c_{0}\mu > 0$, so $R_{c} - c_{3} < 0$, and we deduce $c_{0}c_{2} > 0$ which is a contradiction. $P_{1}$ cannot be a stable node, because in that case we would have the conditions $c_{0} < 0$, $a_{0} + c_{0}\mu < 0$, and $c_{2}(R_{c} - c_{3}) < 0$ which lead to a contradiction in the following way: if $c_{2} > 0$ then $R_{c} - c_{3} < 0$ and squaring we deduce $c_{0}c_{2} > 0$ which is not possible because $c_{0} < 0$ and we are supposing $c_{2} > 0$. An analogous reasoning works in the case $c_{2} < 0$. If $P_{1}$ is an unstable node then $P_{2}$ can be either a saddle or an unstable node, but not a stable node because it requires $a_{0} + c_{0}\mu$ to be negative, but we already know that this expression is positive because it is a condition in order that $P_{1}$ be an unstable node. This leads to cases 2.1 to 2.4 of Table 3.

We continue with the case $c_{0} > 0$, in which $P_{0}$ is an unstable node. If $P_{1}$ is a saddle, then $P_{2}$ can be a saddle or an unstable node. If $P_{2}$ is a stable node then we have the conditions $c_{0} > 0$, $c_{2}(a_{0} + c_{0}\mu)(R_{c} - c_{3}) < 0$, $a_{0} + c_{0}\mu < 0$ and $c_{2} < 0$. Thus we have $R_{c} - c_{3} < 0$ and squaring we obtain $c_{0}c_{2} > 0$ which is a contradiction. This leads to cases 2.5 and 2.6. If $P_{1}$ is a stable node it can be proved similarly to previous cases, that $P_{2}$ cannot be an unstable node. This leads to cases 2.7 and 2.8. $P_{4}$ cannot be an unstable node, because in that case we would have the conditions $c_{0} > 0$, $a_{0} + c_{0}\mu > 0$ and $c_{2}(R_{c} - c_{3}) > 0$ which lead to a contradiction in the following way: if $c_{2} > 0$ then $R_{c} - c_{3} > 0$, and squaring we deduce $c_{0}c_{2} < 0$.
which is not possible because $c_0 > 0$ and we are supposing $c_2 > 0$. An analogous reasoning works in the case $c_2 < 0$.

At last we have the case $c_0 = 0$. Necessarily $c_3 \neq 0$ so the origin is a saddle-node. Also we have that $P_1$ coincides with the origin. For the singular point $P_2$ we have that it is a saddle if $c_2 < 0$, and an unstable node if $c_2 > 0$. This leads to cases 2.9 and 2.10.

We study case 3 of Table 1 in which $c_3^2 = 4c_0c_2$ and $c_1\mu \neq 0$. Then $c_0 = 0$ if and only if $c_3 = 0$. We consider $a_0 > 0$ and $c_0 < 0$, then the origin is a saddle and $P_3$ a saddle-node (as $c_3 \neq 0$). The singular point $P_4$ is either a saddle or a stable node, depending on the sign of $\mu(a_0 + c_0\mu)$. The same is valid in the case $a_0 > 0$ and $c_0 < 0$, except for the origin which is now an unstable node. We get the cases 3.1 to 3.4 of Table 1. We continue with the case in which $a_0 = 0$ and so $P_0$ is a saddle-node, $P_4$ coincides with $P_0$ and $P_3$ is a saddle-node. This correspond with case 3.5. At last we have the condition $c_0 = 0$, under which $P_3$ coincides with $P_0$. If $c_2 < 0$ then it is a topological saddle, and if $c_2 > 0$ it is a topological unstable node. In any case $P_4$ can be either a saddle or a stable node. This leads to cases 3.6 to 3.9.

Now we address the case 4 of Table 1 in which $c_3^2 < 4c_0c_2$, $c_1\mu = 0$, and $a_0 \neq 0$. The origin is a saddle if $c_0 < 0$, and an unstable node if $c_0 > 0$. If $c_0 = 0$ then $c_3 = 0$, so we distinguish two semi-hyperbolic possibilities for the origin: if $c_2 < 0$ it is a topological saddle, and if $c_2 > 0$ it is a topological unstable node. The classification of $P_3$ is totally determined by the one of $P_0$, because it only depends on whether $c_3$ is zero or not. We get cases 4.1 to 4.4.

In case 5 of Table 1 the conditions $c_3^2 < 4c_0c_2$ and $c_1\mu \neq 0$ hold. The singular points are $P_0$ and $P_4$. From condition $c_3^2 < 4c_0c_2$ we obtain that $c_0 \neq 0$. If $a_0 = 0$ then the origin is a saddle-node and $P_4$ coincides with the origin. If $a_0 \neq 0$ then both singular points are hyperbolic, and it leads to cases 5.2 to 5.5.

Finally in case 6 of Table 1 we have the conditions $c_3^2 < 4c_0c_2$, $c_1\mu = 0$, and $a_0 \neq 0$. The unique singular point is the origin and as $c_0$ cannot be zero, it is either a saddle or an unstable node.

\[ \square \]

6. STUDY OF LOCAL INFINITE SINGULAR POINTS

To study the behavior of the trajectories of system \((1.3)\) near infinity we consider its Poincaré compactification. For the moment we assume the same hypothesis (H3) than in previous sections. According to equations \((2.1)\) and \((2.2)\), we obtain the compactification in the local charts $U_1$ and $U_2$ respectively. From Section 2 it is enough to study the singular points over $v = 0$ in the chart $U_1$ and the origin of the chart $U_2$.

In chart $U_1$ system \((1.3)\) writes

\[
\begin{align*}
\dot{u} &= c_2(\mu + 1)u^3 + c_3(\mu + 1)v^2u + (c_0 - a_0)uv^2 + c_1(\mu + 1)uv, \\
\dot{v} &= c_2\mu v^2u + c_3\mu uv^2 - a_0v^3 + c_1\mu v^2.
\end{align*}
\]

Taking $v = 0$ we obtain $\dot{u}_{|v=0} = c_2(\mu + 1)u^3$ and $\dot{v}_{|v=0} = 0$. Therefore if $\mu = -1$ all points at infinity are singular points, and we will not deal with this situation in this paper. In other case, if $\mu \neq -1$ the only singular point is the origin of $U_1$, which we denote by $O_1$. The linear part of system \((6.1)\) at the origin is identically zero, so we must use the blow-up technique to study it, leading to the following result
which is proved in Subsections 6.1 and 6.2. From now on we include the condition

Table 2. Classification in case 1 of Table 1 according to the local phase portraits of finite singular points.

$\mu \neq -1$ in our hypothesis, so we will work under the condition (H1):

$c_2 \neq 0$, $a_0 \geq 0$, $c_1 \geq 0$, $c_3 \geq 0$, $a_0 + c_0 \mu \neq 0$, $a_0 c_1 \mu \neq 0$, $\mu \neq -1$.

**Lemma 6.1.** Under assumption (H1) the origin of the chart $U_1$ is an infinite singular point of system (6.3), and it has 47 distinct local phase portraits described in Figure 7.

For system (6.1), if $c_1 \neq 0$ the characteristic polynomial is $F = -c_1 u w^2 \neq 0$, so the origin is a nondicritical singular point. If $c_1 = 0$ the characteristic polynomial is $F = -c_2 u^2 v - c_2 u^3 v - c_0 u v^3$, which cannot be identically zero because $c_2 \neq 0$. We will study this two cases separately.

### 6.1. Case $c_1$ Non-zero

Consider $c_1 \neq 0$. We introduce the new variable $w_1$ by means of the variable change $u w_1 = v$, and get the system

\[
\begin{align*}
\dot{u} &= (c_0 - a_0) u^3 w_1^2 + c_3 (\mu + 1) u^3 w_1 + c_2 (\mu + 1) u^3 w_1 + c_1 (\mu + 1) u^2 w_1, \\
\dot{w}_1 &= -c_0 u^2 w_1^3 - c_3 u^2 w_1^2 - c_2 u^2 w_1 - c_1 u w_1^2. 
\end{align*}
\]

(6.2)

Now we cancel the common factor $u$, getting the system

\[
\begin{align*}
\dot{u} &= (c_0 - a_0) u^2 w_1^2 + c_3 (\mu + 1) u^2 w_1 + c_2 (\mu + 1) u^2 + c_1 (\mu + 1) w_1, \\
\dot{w}_1 &= -c_0 u w_1^3 - c_3 u w_1^2 - c_2 u w_1 - c_1 w_1^2, 
\end{align*}
\]

(6.3)

for which the only singular point on the exceptional divisor is the origin, and it is linearly zero, so we have to repeat the process. Now the characteristic polynomial is $F = -c_2 (\mu + 2) u^2 w_1 - c_1 (\mu + 2) u w_1^2$, so the origin is a nondicritical singular

</tbody>
</table>

point if $\mu \neq -2$, and it is dicritical if $\mu = -2$. In both cases we introduce the new
variable $w_2$ doing the change $uw_2 = w_1$, obtaining the system
\[
\dot{u} = (c_0 - a_0)u^4 w_2^2 + c_3(\mu + 1)u^3 w_2 + c_2(\mu + 1)u^2 + c_1(\mu + 1)u^2 w_2, \\
\dot{w}_2 = (a_0 - 2c_0)u^3 w_2^3 - c_3(\mu + 2)u^2 w_2^2 - c_1(\mu + 2)uw_2^2 - c_2(\mu + 2)w_2. \tag{6.4}
\]
In the nondicritical case we have to cancel the common factor $u$ obtaining
\[
\dot{u} = (c_0 - a_0)u^3 w_2^2 + c_3(\mu + 1)u^2 w_2 + c_2(\mu + 1)u + c_1(\mu + 1)uw_2, \\
\dot{w}_2 = (a_0 - 2c_0)u^2 w_2^3 - c_3(\mu + 2)uw_2^2 - c_1(\mu + 2)w_2^2 - c_2(\mu + 2)w_2. \tag{6.5}
\]
But in the dicritical case, when $\mu = -2$, we must cancel the common factor $u^2$ from system \((6.4)\), and we obtain the system
\[
\dot{u} = (c_0 - a_0)u^2 w_2^2 - c_3uw_2 - c_2 - c_1w_2, \\
\dot{w}_2 = (a_0 - 2c_0)uw_2^3. \tag{6.6}
\]

6.1.1. Nondicritical case. In this case it is necessary to study the singular points of system \((6.5)\) on the exceptional divisor. The origin is always a singular point, and we denote it by $Q_0$. As $\mu + 2 \neq 0$ there is another singular point, $Q_1 = (0, -c_2/c_1)$ and we determine their local phase portraits.

The origin $Q_0$ is always hyperbolic. It is a stable node if $\mu \in (-\infty, -2) \cup (-1, +\infty)$, a stable node if $c_2 > 0$ and $\mu \in (-2, -1)$, and an unstable node if $c_2 < 0$ and $\mu \in (-2, -1)$.

The singular point $Q_1$ is semi-hyperbolic. If $c_2(a_0 + c_0\mu) > 0$ then $Q_1$ is a topological saddle, if $c_2(\mu + 2) > 0$ and $(\mu + 2)(a_0 + c_0\mu) < 0$ then it is a topological unstable node, and if $c_2(\mu + 2) < 0$ and $(\mu + 2)(a_0 + c_0\mu) > 0$ it is a topological stable node. These conditions come together in the next 7 subcases.

1. If $\mu \in (-\infty, -2) \cup (-1, +\infty)$ and $c_2(a_0 + c_0\mu) > 0$, then $Q_0$ is a saddle and $Q_1$ a topological saddle. To determine the phase portrait around the $w_2$-axis for system \((6.5)\), we must fix the sign of $c_2$, which determines the position of the singular point $Q_1$, and also the sign of $\mu + 1$, which determines the sense of the flow along the $x$-axis. Thus we deal with the following subcases.

Subcase (1.1). Let $\mu < -2$ (so $\mu + 1 < 0$) and $c_2 > 0$. Then the singular point $Q_1$ is on the negative part of the $w_2$-axis and the expression $\dot{u}|_{w_2=0} = c_2(\mu + 1)u$ determines the sense of the flow, so the phase portrait is the one in Figure 2(a).

To return to system \((6.4)\) we multiply by $u$, thus the orbits in the second and third quadrants change their orientation. Moreover all the points on the $w_2$-axis become singular points. The resultant phase portrait is given in Figure 2(b).

Subcase (1.2). Let $\mu > -2$ (so $\mu + 1 > 0$) and $c_2 > 0$. Then the singular point $Q_1$ is on the positive part of the $w_2$-axis and the expression $\dot{u}|_{w_2=0} = c_2(\mu + 1)u^2$ determines the sense of the flow. Following the results

Figure 1. Local phase portraits of the infinite singular point $O_1$
(to be continued)

mentioned in Subsection 2.3, the separatrix of the singular point $Q_1 = (0, -c_2/c_1)$
in the $(u, w_2)$-plane, becomes the separatrix with slope $-c_2/c_1$ in the $(u, w_1)$-plane.
Figure 1. (cont.) Local phase portraits of the infinite singular point $O_1$.

We get the phase portrait given in Figure 2(c), and multiplying again by $u$, the one given in Figure 2(d).

Finally we must go back to the $(u, v)$-plane, swapping the second and the third quadrants and contracting the exceptional divisor to the origin. The orbits tending
to the origin in forward or backward time, became orbits tending to the origin in forward or backward time with slope zero, i.e., tangent to the \( u \)-axis. According to the expressions \[ \frac{\dot{u}}{v} = c_1 \mu v^2 - a_0 v^3 \] and \[ \frac{\dot{u}}{v} = c_2 (\mu + 1) v^3 , \] which determine the sense of the flow along the axes, we obtain the local phase portrait at the origin for system (6.1) given in Figure 1(L1).

Subcase (1.2) If we maintain \( \mu < -2 \) but take \( c_2 < 0 \), the reasoning is essentially similar to the one we have given in the previous case, and we obtain the phase portrait (L2) of Figure 1.

Subcase (1.3) Let \( \mu > -1 \) and \( c_2 > 0 \). This determines the position of the singular point \( Q_1 \) and the sense of the flow along the axes, so around the \( w_2 \)-axis we obtain the phase portrait given in Figure 3(a).

As in the previous subcase we multiply by \( u \) obtaining the phase portrait given in Figure 3(b), as the orbits in the second and third quadrants change their orientation and all the point in the \( w_2 \)-axis become singular points.

To undo the variable change we analyze the sense of the flow along the axes according to the expression \[ \frac{\dot{u}}{w_1} = c_2 (\mu + 1) w_2^2 , \] which determines that the flow goes away from the origin along the \( w_2 \)-axis, nevertheless the sense of the flow along the \( u \)-axis is not determined by \( \frac{\dot{v}}{u} = c_1 \mu v^2 - a_0 v^3 \), it depends on the constant \( \mu \). If \( \mu > 0 \) the flow goes in the positive sense of the \( v \)-axis, if \( \mu < 0 \) in the opposite sense and, if \( \mu = 0 \) the flow goes to the origin. Thus we must distinguish three subcases and in each of them, modifying the orbits properly, we obtain, respectively, the phase portraits given in Figure 3(c), (L3) and (L4).

Subcase (1.4). Let \( \mu > -1 \) and \( c_2 < 0 \). By a similar reasoning to the previous one, we obtain the phase portraits (L6) and (L7) of Figure 1.

(2) If \( \mu \in (-\infty, -2) \cup (-1, +\infty) \), \( c_2 (\mu + 2) > 0 \) and \( (\mu + 2)(a_0 + c_0 \mu) < 0 \), then \( Q_0 \) is a saddle and \( Q_1 \) a topological unstable node. We must distinguish two cases according to the sign of \( c_2 \).

Subcase (2.1). We consider \( c_2 < 0 \) so \( \mu < -2 \) and \( a_0 + c_0 \mu > 0 \). The singular point \( Q_1 \) is on the positive \( w_2 \)-axis and it is an unstable node, so the sense of the
flow along the axes is determined, and we obtain the phase portrait given in Figure 4(a). Multiplying by $u$ we obtain Figure 4(b).

We see that for system (6.3) the flow goes in the negative sense along the $w_1$-axis and in the positive sense along the $u$-axis, according to the expressions $\dot{u}\big|_{w_1=0} = c_2(\mu + 1)u^2$ and $\dot{w}_1\big|_{u=0} = -c_1w_1^2$. We undo the variable change modifying the orbits properly, and we note that it must exist an hyperbolic or elliptic sector in both first and third quadrants, thus it can appear the configuration given in Figure 4(c) or the one given in Figure 5(a). From the first of them multiplying by $u$ we obtain 4(d), and if we undo the variable change in a similarly way than in the previous cases, we obtain the phase portrait in Figure 1(L8).

If we consider hyperbolic sectors we continue undoing the blow up from Figure 5(a), obtaining successively the phase portraits 5(b) and 5(c). However in our study we have proved, by means of the index theory, that only the case with elliptic sectors is feasible in the global phase portraits obtained. More detailed explanations will be given in Section 7 but, roughly speaking we know that the index of the vector field on the sphere must be 2, and this index is the sum of the indices of all singularities, which depend on the sectors that they have, so if the index is 2 considering two elliptic sectors in a particular singular point, it cannot be 2 if we change those sectors for hyperbolic ones. In conclusion the only phase portrait that will appear in this case is (L8) of Figure 1.

From now on we will omit the reasonings about how to undo the variable changes for obtaining the final phase portrait, because they are similar to the ones of the previous cases. The results obtained are the following.

From the flow along the axes, we obtain the phase portraits as shown in Figures 4 and 5.

**FIGURE 4.** Desingularization of the origin of system (6.1) with $c_1 \neq 0$. Nondicritical case (2.1).

**FIGURE 5.** Desingularization of the origin of system (6.1) with $c_1 \neq 0$. Alternative to nondicritical case (2.1).
Subcase (2.2). Let $c_2 > 0$ so $\mu > -1$ and $a_0 + c_0\mu < 0$. We obtain the phase portraits (L9) and (L10) of Figure 1. In (L9) it is possible to consider hyperbolic sectors instead of the elliptic ones, but applying index theory to the global phase portraits obtained in our study, we note that only the phase portrait with elliptic sectors is feasible.

(3) If $\mu \in (-\infty, -2) \cup (-1, +\infty)$, $c_2(\mu + 2) < 0$ and $(\mu + 2)(a_0 + c_0\mu) > 0$, then $Q_0$ is a saddle and $Q_1$ a topological stable node. If $c_2 > 0$ we obtain the phase portrait (L11) of Figure 1 and if $c_2 < 0$ we obtain the phase portraits (L12), (L13) and (L14) of Figure 1. In (L11) and (L12) it would be possible that the elliptic sectors appearing were hyperbolic sectors, but again we have proved that only the elliptic option is feasible according to the index theory.

(4) If $c_2 > 0$, $\mu \in (-2, -1)$ and $a_0 + c_0\mu > 0$, then $Q_0$ is a stable node and $Q_1$ a topological saddle. We obtain the phase portrait (L15) of Figure 1.

(5) If $c_2 > 0$, $\mu \in (-2, -1)$ and $a_0 + c_0\mu < 0$, then $Q_0$ is a stable node and $Q_1$ a topological saddle. We obtain the phase portrait (L16) of Figure 1.

(6) If $c_2 < 0$, $\mu \in (-2, -1)$ and $a_0 + c_0\mu < 0$, then $Q_0$ is an unstable node and $Q_1$ a topological stable node. We obtain the phase portrait (L8) of Figure 1.

(7) If $c_2 < 0$, $\mu \in (-2, -1)$ and $a_0 + c_0\mu > 0$, then $Q_0$ is an unstable node and $Q_1$ a topological stable node. We obtain the phase portrait (L8) of Figure 1.

6.1.2. Dicritical case. Now we must study the singular points on the exceptional divisor of system (6.6). In this case there is only one singular point, $R = (0, -c_2/c_1)$ which is non-degenerated. We shall distinguish several subcases.

- If $c_2^3 < -4c_2(a_0 - 2c_0)$ and $c_2c_3 < 0$, then $P$ is a stable focus. We shall distinguish two cases depending on the sign of the parameter $c_2$, because it determines if the singular point is on the positive or negative $u$-axis. We consider $c_2 > 0$. In Figure 6 the blowing-down process is represented. The phase portrait around the $u$-axis is the one given in Figure 6(a), multiplying by $u^2$ we obtain (b), undoing the second variable change we obtain (c), multiplying by $u$ we obtain (d) and finally, undoing the first variable change we obtain the phase portrait (L11) of Figure 1. Taking $c_2 < 0$ and by the same method we obtain the phase portrait (L8) of Figure 1.

![Figure 6. Desingularization of the origin of system (6.1) with $c_1 \neq 0$. Dicritical case (1), $c_2 > 0$.](image)

From now on we omit explanations in cases in which similar arguments are valid, and same results are obtained. In order to simplify the notation we define $\beta = \sqrt{c_2^2 + 4c_2(a_0 - 2c_0)}$. 
• If \( c_3^2 < -4c_2(a_0 - 2c_0) \) and \( c_2c_3 > 0 \), then \( P \) is an unstable focus. The reasoning is analogous to the one of the previous case and we obtain the same phase portraits: (L11) if \( c_2 > 0 \), and (L8) if \( c_2 < 0 \).

• If \( c_3^2 = -4c_2(a_0 - 2c_0) \) and \( c_2c_3 < 0 \) or if \( c_3^2 > -4c_2(a_0 - 2c_0) \), \( c_2(c_3 - \beta) < 0 \) and \( c_3(c_3 + \beta) < 0 \), then \( P \) is a stable node. If \( c_3^2 = -4c_2(a_0 - 2c_0) \) and \( c_2c_3 > 0 \) or if \( c_3^2 > -4c_2(a_0 - 2c_0) \), \( c_2(c_3 - \beta) > 0 \) and \( c_2(c_3 + \beta) > 0 \), then \( P \) is an unstable node. In both cases the phase portrait obtained is again (L11) if \( c_2 > 0 \), and (L8) if \( c_2 < 0 \).

• If \( c_3 = 0 \) and \( c_2(a_0 - 2c_0) < 0 \) then \( P \) is a linear center. In this case the singular point \( P \) could be a center or a focus, but the final phase portrait obtained when \( P \) is a center is the same as the one we obtained previously for the case with a focus, so the result is (L11) if \( c_2 > 0 \), and (L8) if \( c_2 < 0 \).

• If \( c_3^2 > -4c_2(a_0 - 2c_0) \) and \( (c_3 - \beta)(c_3 + \beta) < 0 \), or if \( c_3 = 0 \) and \( c_2(a_0 - 2c_0) > 0 \), then \( P \) is a saddle. The blowing-down considering \( c_2 > 0 \) is represented in Figure 7. The final result is (L17) of Figure 1. If we take \( c_2 < 0 \) we obtain the phase portrait (L18).

![Desingularization of the origin of system (6.1) with \( c_1 \neq 0 \). Dicritical case (5), \( c_2 > 0 \).](image)

**Figure 7.** Desingularization of the origin of system (6.1) with \( c_1 \neq 0 \). Dicritical case (5), \( c_2 > 0 \).

### 6.2. Case \( c_1 \) zero.

We consider system (6.1) and do the same variable change that we did in the case with \( c_1 \neq 0 \), the result is obviously system (6.2) but taking \( c_1 = 0 \), i.e.

\[
\begin{align*}
\dot{u} &= (c_0 - a_0)u^3w_1^2 + c_3(\mu + 1)u^3w_1 + c_2(\mu + 1)u^3, \\
\dot{w}_1 &= -c_0u^2w_1^3 - c_3u^2w_1^3 - c_2u^2w_1.
\end{align*}
\]

(6.7)

In this case we can cancel a common factor \( u^2 \) getting the system

\[
\begin{align*}
\dot{u} &= (c_0 - a_0)uw_1^2 + c_3(\mu + 1)uw_1 + c_2(\mu + 1)u, \\
\dot{w}_1 &= -c_0w_1^3 - c_3w_1^3 - c_2w_1.
\end{align*}
\]

(6.8)

for which we must study the singular points on the exceptional divisor, i.e. on the straight line \( u = 0 \).

The origin \( S_0 = (0, 0) \) is always a singular point. The other singular points on this line are those for which \( w_1 \) is a solution of \( c_0w_1^2 + c_3w_1 + c_2 = 0 \). If \( c_0 \neq 0 \) and \( c_3^2 > 4c_0c_2 \) then \( S_1 = (0, -(Rc + c_3)/(2c_0)) \) and \( S_2 = (0, (Rc - c_3)/(2c_0)) \) are singular points. If \( c_0 \neq 0 \) and \( c_3^2 = 4c_0c_2 \), then \( S_3 = (0, -c_3/2c_0) \) is a singular point, and finally, if \( c_0 \) and \( c_3 \) are non-zero, \( S_4 = (0, -c_2/c_3) \) is a singular point.
stable node if \( c \) case the necessary hypothesis for its existence.

We study separately the local phase portrait of each singular point assuming in each case the blowing-down we obtain the phase portrait (L23) of Figure (1).

Given in Figure (1)(L19), and with \( w_2 \) around the perbolic saddle if \( c \) and \( (a_0 + c_0 \mu) < 0 \), a stable node if \( c_0 > 0 \) and \( (a_0 + c_0 \mu) > 0 \), and an unstable node if \( c_0 < 0 \) and \( (a_0 + c_0 \mu) < 0 \). \( S_1 \) is a saddle if \( c_0(a_0 + c_0 \mu) < 0 \), a stable node if \( c_0 > 0 \) and \( (a_0 + c_0 \mu) > 0 \), and an unstable node if \( c_0 < 0 \) and \( (a_0 + c_0 \mu) < 0 \). \( S_2 \) is a saddle if \( c_0(a_0 + c_0 \mu)(R_e - c_3) < 0 \), a stable node if \( c_0(R_e - c_3) > 0 \) and \( (a_0 + c_0 \mu) > 0 \), and an unstable node if \( c_0(R_e - c_3) < 0 \) and \( (a_0 + c_0 \mu) < 0 \).

The singular point \( S_3 \) is a semi-hyperbolic saddle-node and finally, \( S_4 \) is a hyperbolic saddle if \( c_2 > 0 \), and a hyperbolic stable node if \( c_2 < 0 \).

Using these informations we study the next cases from the five given in Table 8.

First of all we study case (A) in which the only singular point is the origin, so we have the next three possibilities.

If \( c_0 = c_3 = 0 \) and \( \mu > -1 \), then \( S_0 \) is a saddle. To determine the phase portrait around the \( w_1 \)-axis for system (6.8) we must fix the sign of \( c_2 \), which determines the sense of the flow along the axes. Considering \( c_2 > 0 \) we obtain the phase portrait given in Figure (1)(L19), and with \( c_2 < 0 \) we obtain the phase portrait (L20).

If \( c_0 = c_3 = 0 \), \( \mu < -1 \) and \( c_2 > 0 \), then \( S_0 \) is a stable node, and we obtain the phase portrait (L21) of Figure (1).

If \( c_0 = c_3 = 0 \), \( \mu < -1 \) and \( c_2 < 0 \), then \( S_0 \) is an unstable node, and we obtain the phase portrait (L22) of Figure (1).

In case (B), fixed the phase portrait of \( S_4 \), only two phase portraits will be possible for the origin, as the sign of \( c_2 \) is determined, and so we obtain the four following cases.

If \( c_0 = 0, c_3 \neq 0, \mu > -1 \) and \( c_2 > 0 \), then \( S_0 \) and \( S_4 \) are both saddle points and from the blowing-down we obtain the phase portrait (L23) of Figure (1).

If \( c_0 = 0, c_3 \neq 0, \mu > -1 \) and \( c_2 < 0 \), then \( S_0 \) is a saddle and \( S_4 \) a stable node. We obtain the phase portrait (L24) of Figure (1).

If \( c_0 = 0, c_3 \neq 0, \mu < -1 \) and \( c_2 > 0 \), then \( S_0 \) is a stable node and \( S_4 \) a saddle. We obtain the phase portrait (L25) of Figure (1).

If \( c_0 = 0, c_3 \neq 0, \mu < -1 \) and \( c_2 < 0 \), then \( S_0 \) is an unstable node and \( S_4 \) a stable node. We obtain the phase portrait (L26) of Figure (1).

Again in case (C) the only singular point is the origin so we distinguish three cases, and obtain the same local phase portrait that in case (A), but under different conditions. If \( c_0 \neq 0, c_2 < 4c_0c_2 \) and \( \mu > -1 \), then \( S_0 \) is a saddle. Attending to

the sign of $c_2$, which determines the sense of the flow on the axes, we consider the following cases: if $c_2 > 0$ we obtain the phase portrait (L19) of Figure 1, and if $c_2 < 0$ we obtain the phase portrait (L20) of Figure 1.

If $c_0 \neq 0$, $c_3^2 < 4c_0c_2$, $\mu < -1$ and $c_2 > 0$, then $S_0$ is a stable node. We obtain the phase portrait (L21) of Figure 1.

If $c_0 \neq 0$, $c_3^2 < 4c_0c_2$, $\mu < -1$ and $c_2 < 0$, then $S_0$ is an unstable node. We obtain the phase portrait (L22) of Figure 1.

In case (D) apart from the origin, there exists the singular point $S_3$, which is always a saddle node, so again we obtain only three cases.

If $c_0 \neq 0$, $c_3^2 = 4c_0c_2$ and $\mu > -1$, then $S_0$ is a saddle and $S_3$ a saddle-node. We must distinguish four subcases according to the signs of $c_0$ and $a_0 + c_0\mu$, which determine the position of the saddle-node $S_3$ and its sectors.

If $c_0 > 0$ and $a_0 + c_0\mu > 0$ we obtain the phase portrait (L27) of Figure 1, if $c_0 > 0$ and $a_0 + c_0\mu < 0$ we obtain the phase portrait (L28) of Figure 1, if $c_0 < 0$ and $a_0 + c_0\mu > 0$ we have the phase portrait (L29), and if $c_0 < 0$ and $a_0 + c_0\mu < 0$ the phase portrait (L30).

If $c_0 \neq 0$, $c_3^2 = 4c_0c_2$, $\mu < -1$ and $c_2 > 0$, then $S_0$ is a stable node and $S_3$ a saddle-node. We distinguish two subcases setting the sign of $a_0 + c_0\mu$ which determines the position of the sectors of the saddle-node $S_3$. If $a_0 + c_0\mu > 0$ we obtain the phase portrait (L31) of Figure 1, and if $a_0 + c_0\mu < 0$ we obtain the phase portrait (L32) of Figure 1.

If $c_0 \neq 0$, $c_3^2 = 4c_0c_2$, $\mu < -1$ and $c_2 < 0$, then $S_0$ is an unstable node and $S_3$ a saddle-node. The only possibility is that $a_0 + c_0\mu > 0$, and we obtain the phase portrait (L33) of Figure 1.

In case (E) there exist three singular points, with three possible phase portraits for each of them, however, many of the combinations are not possible, and only 13 cases will be feasible.

First, due to the conditions which define the local phase portrait in each singular point, it is obvious that if $S_1$ is a stable node, then $S_2$ cannot be an unstable node, and if $S_1$ is an unstable node, $S_2$ cannot be a stable node, due to the sign of $a_0 + c_0\mu$.

If $S_0$ and $S_2$ were stable nodes and $S_1$ a saddle, the conditions $c_2 > 0$, $R_e - c_3 < 0$, and $c_0 < 0$ will hold. Squaring both terms in the condition $R_e < c_3$ we obtain $c_3^2 - 4c_0c_2 < c_3^2$, and then $c_0<0$, which is a contradiction. The same reasoning is valid in the next two cases.

If $S_0$ and $S_2$ are unstable nodes and $S_1$ a saddle, then the conditions $c_2 < 0$, $R_e - c_3 < 0$ and $c_0 > 0$ hold, and if $S_0$ is an unstable node, $S_1$ a stable node and $S_2$ a saddle, then the same three conditions hold.

If $S_0$, $S_1$ and $S_2$ are stable nodes, the conditions $c_2 > 0$, $R_e - c_3 > 0$ and $c_0 > 0$ hold. Now we take condition $R_e < c_3$ and squaring both terms we obtain $c_3^2 - 4c_0c_2 < c_3^2$, and then $c_0c_2 > 0$, which is a contradiction.

If $S_0$ is a stable node and $S_1$ an unstable node, the conditions $\mu < -1$, $c_0 < 0$ and $a_0 + c_0\mu < 0$ hold. Then according to the signs of $c_0$ and $\mu$ which are fixed, $a_0 < -c_0\mu < 0$ which contradicts the hypothesis (H1). The same reasoning is valid if $S_0$ and $S_1$ are unstable nodes, because the same conditions hold. Now we will study the feasible cases.

(E1) If $c_0 \neq 0$, $c_3^2 > 4c_0c_2$, $\mu > -1$, $c_0(a_0 + c_0\mu)(2c_0c_2 - c_3^2 - c_3R_e) > 0$ and $c_0(a_0 + c_0\mu)(R_e - c_3)(2c_0c_2 - c_3^2 + c_3R_e) > 0$, then $S_0$, $S_1$ and $S_2$ are saddles. We must distinguish two subcases depending on the position of the singular points $S_1$
and \( S_2 \) on the \( w_1 \)-axis. First if \( S_1 \) is on the negative \( w_1 \)-axis and \( S_2 \) on the positive \( w_1 \)-axis, that corresponds with conditions \( c_0 > 0, R_c - c_3 > 0 \) and \( c_2 < 0 \), we obtain the phase portrait (L34) of Figure 1. Note that if \( R_c - c_3 > 0 \), the singular points \( S_1 \) and \( S_2 \) are one on the positive part of the axis and the other on the negative part, but in any case the absolute value of the second coordinate of \( S_1 \) is greater or equal than the absolute value of the second coordinate of \( S_2 \), and this determines the relation between the slopes of orbits in the phase portraits. Conversely if we have \( S_1 \) on the positive \( w_1 \)-axis and \( S_2 \) on the negative one, i.e. under the conditions \( c_0 < 0, R_c - c_3 > 0 \) and \( c_2 > 0 \), we obtain the phase portrait (L35) of Figure 1.

(E2) If \( c_0 \neq 0, c_3 > 4c_0c_2, \mu > -1, c_0(a_0 + c_0\mu)(2c_0c_2 - c_3^2 + c_3R_c) > 0, c_0(R_c - c_3) > 0 \) and \((a_0 + c_0\mu)(2c_0c_2 - c_3^2 + c_3R_c) < 0\), then \( S_0 \) and \( S_1 \) are saddles and \( S_2 \) is a stable node. If \( c_0 > 0 \) then \( R_c - c_3 > 0 \) and so \( c_3^2 - 4c_0c_2 > c_3^2 > c_2 < 0 \). If \( a_0 + c_0\mu > 0 \) then \( 2c_0c_2 - c_3^2 - c_3R_c > 0 \) which is not possible because \( 2c_0c_2 < 0 \) and we subtract two positive terms. Conversely if \( a_0 + c_0\mu < 0 \) then \( 2c_0c_2 - c_3^2 < c_3R_c \) and \( 2c_0c_2 - c_3^2 < -c_3R_c \), so \( |2c_0c_2 - c_3^2| < c_3R_c \). Squaring we obtain \( 4c_0^2c_2^2 < 0 \) which is not possible. If \( c_0 < 0 \) then \( R_c - c_3 < 0 \) and we deduce \( c_2 < 0 \). If \( a_0 + c_0\mu < 0 \) then \( 2c_0c_2 - c_3^2 - c_3R_c > 0 \), but \( c_3 - 2c_0c_2 > c_3 - 4c_0c_2 > 0 \) so \( 2c_0c_2 - c_3^2 < 0 \) and subtracting \( c_3R_c > 0 \) the result cannot be positive. In conclusion we deduce that \( c_0, c_2 < 0 \) and \( a_0 + c_0\mu < 0 \). Hence we have \( -(R_c + c_3)/(2c_0) > (R_c - c_3)/(2c_0) > 0 \). This determines the only possible position of the singular points which are both in the positive \( w_1 \)-axis. Undoing the blow up we obtain the phase portrait (L36) of Figure 1.

(E3) If \( c_0 \neq 0, c_3^2 > 4c_0c_2, \mu > -1, c_0(a_0 + c_0\mu)(2c_0c_2 - 2c_3^2 - 3c_3R_c) > 0, c_0(R_c - c_3) < 0 \) and \((a_0 + c_0\mu)(2c_0c_2 - c_3^2 + c_3R_c) < 0\), then \( S_0 \) and \( S_1 \) are saddles and \( S_2 \) is an unstable node. Therefore we deduce that \( 0 > (R_c - c_3)/(2c_0) > -(R_c + c_3)/(2c_0) \), so both singular points are on the negative \( w_1 \)-axis, \( S_1 \) under \( S_2 \). We obtain the phase portrait (L37) of Figure 1.

(E4) If \( c_0 \neq 0, c_3^2 > 4c_0c_2, \mu > -1, c_0 > 0, (a_0 + c_0\mu)(2c_0c_2 - c_3^2 - c_3R_c) < 0 \) and \( c_0(R_c - c_3)(a_0 + c_0\mu)(2c_0c_2 - c_3^2 + c_3R_c) > 0 \), then \( S_0 \) and \( S_2 \) are saddles and \( S_1 \) is a stable node. Then we deduce that \(-(R_c + c_3)/(2c_0) < (R_c - c_3)/(2c_0) < 0\), so both singular points are on the negative \( w_1 \)-axis, \( S_1 \) under \( S_2 \). We obtain the phase portrait (L38) of Figure 1.

(E5) If \( c_0 \neq 0, c_3^2 > 4c_0c_2, \mu > -1, c_0 > 0, (a_0 + c_0\mu)(2c_0c_2 - c_3^2 - c_3R_c) < 0, c_0(R_c - c_3) > 0 \) and \((a_0 + c_0\mu)(2c_0c_2 - c_3^2 + c_3R_c) < 0\), then \( S_0 \) is a saddle and \( S_1 \) and \( S_2 \) are stable nodes. We obtain the phase portrait (L45) of Figure 1.

(E6) If \( c_0 \neq 0, c_3^2 > 4c_0c_2, \mu > -1, c_0 < 0, (a_0 + c_0\mu)(2c_0c_2 - c_3^2 - c_3R_c) > 0 \) and \((a_0 + c_0\mu)(R_c - c_3)(2c_0c_2 - c_3^2 + c_3R_c) < 0\), then \( S_0 \) and \( S_2 \) are saddles and \( S_1 \) is an unstable node. Hence we deduce that \( 0 < (R_c - c_3)/(2c_0) < -(R_c + c_3)/(2c_0) \), so both singular points are on the positive \( w_1 \)-axis, \( S_2 \) under \( S_1 \). We obtain the phase portrait (L47) of Figure 1.

(E7) If \( c_0 \neq 0, c_3^2 > 4c_0c_2, \mu > -1, c_0 < 0, (a_0 + c_0\mu)(2c_0c_2 - c_3^2 - c_3R_c) > 0, R_c - c_3 > 0 \) and \((a_0 + c_0\mu)(2c_0c_2 - c_3^2 + c_3R_c) > 0\), then \( S_0 \) is a saddle and \( S_1 \) and \( S_2 \) are unstable nodes. We obtain the phase portrait (L46) of Figure 1.

(E8) If \( c_0 \neq 0, c_3^2 > 4c_0c_2, c_2 > 0, \mu < -1, c_0(a_0 + c_0\mu)(2c_0c_2 - c_3^2 - c_3R_c) > 0 \) and \( c_0(a_0 + c_0\mu)(R_c - c_3)(2c_0c_2 - c_3^2 + c_3R_c) > 0 \), then \( S_0 \) is a stable node and \( S_1 \) and \( S_2 \) are saddles. We obtain the phase portrait (L39) of Figure 1.

(E9) If \( c_0 \neq 0, c_3^2 > 4c_0c_2, c_2 > 0, \mu < -1, c_0(a_0 + c_0\mu)(2c_0c_2 - c_3^2 - c_3R_c) > 0, c_0(R_c - c_3) < 0 \) and \((a_0 + c_0\mu)(2c_0c_2 - c_3^2 + c_3R_c) > 0\), then \( S_0 \) is a stable node,
$S_1$ is a saddle and $S_2$ is an unstable node. We obtain the phase portrait (L40) of Figure 1.

(E10) If $c_0 \neq 0, c_3^2 > 4c_0c_2, c_2 > 0, \mu < -1, c_0 > 0, (a_0 + c_0\mu)(2c_0c_2 - c_3^2 + c_3R_e) < 0$ and $(a_0 + c_0\mu)(R_e - c_3)(2c_0c_2 - c_3^2 + c_3R_e) > 0$, then $S_0$ and $S_1$ are stable nodes and $S_2$ is a saddle. We obtain the phase portrait (L41) of Figure 1.

(E11) If $c_0 \neq 0, c_3^2 > 4c_0c_2, c_2 < 0, \mu < -1, c_0(a_0 + c_0\mu)(2c_0c_2 - c_3^2 - c_3R_e) > 0$, and $c_0(a_0 + c_0\mu)(R_e - c_3)(2c_0c_2 - c_3^2 + c_3R_e) > 0$, then $S_0$ is an unstable node and $S_1$ and $S_2$ are saddles. We obtain the phase portrait (L42) of Figure 1.

(E12) If $c_0 \neq 0, c_3^2 > 4c_0c_2, c_2 < 0, \mu < -1, c_0(a_0 + c_0\mu)(2c_0c_2 - c_3^2 - c_3R_e) > 0$, $c_0(R_e - c_3) > 0$, and $(a_0 + c_0\mu)(2c_0c_2 - c_3^2 + c_3R_e) < 0$, then $S_0$ is an unstable node, $S_1$ is a saddle and $S_2$ is a stable node. We obtain the phase portrait (L43) of Figure 1.

(E13) If $c_0 \neq 0, c_3^2 > 4c_0c_2, c_2 < 0, \mu < -1, c_0 > 0, (a_0 + c_0\mu)(2c_0c_2 - c_3^2 - c_3R_e) < 0, R_e - c_3 > 0$, and $(a_0 + c_0\mu)(2c_0c_2 - c_3^2 + c_3R_e) < 0$, then $S_0$ is an unstable node and $S_1$ and $S_2$ are stable nodes. We obtain the phase portrait (L44) of Figure 1.

Note that in the phase portraits (L22), (L30), (L33), (L43), (L46) and (L47) of Figure 1 it is possible to consider hyperbolic sectors instead of the elliptic ones, but we have only represented the elliptic cases by the same reason given before, i.e. because applying the index theory to the phase portraits in the sphere $S^2$ described in Section 7 we proved that they are the only feasible.

Once we completed the study in the local chart $U_1$, we study the origin of chart $U_2$ which turned out to be much simpler. The system has the expression

\[
\dot{u} = -c_1(\mu + 1)u^2v + (a_0 - c_0)uv^2 - c_3(\mu + 1)uv - c_2(\mu + 1)u, \\
\dot{v} = -c_1uv^2 - c_0v^3 - c_3v^2 - c_2v. \tag{6.9}
\]

**Lemma 6.2.** The origin of chart $U_2$ is always a hyperbolic infinite singular point of system (1.3). It is a saddle if $\mu < -1$, a stable node if $c_2 > 0$ and $\mu > -1$, and an unstable node if $c_2 < 0$ and $\mu > -1$.

7. Global phase portraits

To prove the global result stated in Theorem 1.1 we will bring together the local information obtained in the previous sections. We start our classification from the cases in Tables 2 to 7. In some of them the conditions determine only one local phase portrait in each one of the infinite singular points but, in many others we shall distinguish several possibilities. In some cases the local information gives rise to only one phase portrait, this occurs when the separatrices can be connected in only one way, but in others several global possibilities appear, and we shall prove which of them are feasible.

In Table 9 we give, for each case in the Tables 2 to 7, the local phase portrait of the infinite singularities $O_1$ and $O_2$ (in most cases this depends on the parameters), and also we give the global phase portrait on the Poincaré disc obtained. And now we detail the reasonings in some cases, although they will not be showed in all cases to avoid repetitions.

**Case 1.1.** The infinite singular point $O_1$ has the local phase portrait (L12) given in Figure 1, and $O_2$ is an unstable node. As we said in Section 6 the elliptic sectors appearing in phase portrait (L12) could be hyperbolic sectors if we attend only to local results, but now having all the global information we can prove that they are elliptic by using the index theory. By Theorem 2.2 the sum of the indices of all
the singular points on the Poincaré sphere has to be 2. To compute this sum we must consider that the finite singular points on the Poincaré disc appear twice on the sphere (on the northern hemisphere and on the southern hemisphere). Thus if we denote by ind$_F$ the sum of the indices of the finite singular points, and by ind$_I$ the sum of the indices of the infinite singular points, the equality $2 \text{ind}_F + \text{ind}_I = 2$ must be satisfied.

In this particular case the finite singular points are a saddle-node whose index is 0, and two saddles whose index is $-1$, so $\text{ind}_F = -2$. We deduce that $\text{ind}_I$ must be 6. The infinite singular points are $O_1$ and $O_2$, the origins of the local charts $U_1$ and $U_2$, and the origins of the symmetric local charts $V_1$ and $V_2$, which have the same index. Since $O_2$ is a node, and so it has index 1, we obtain that the sum of the indices of $O_2$ and its symmetric must be 4, i.e. the index of $O_2$ has to be 2. From the Poincaré formula for the index given in subsection 2.4 we obtain

$$e - h + 1 = 2 \implies e - h = 2.$$ 

Hence only the case with two elliptic sectors on the local phase portrait (L12) is possible, because if we had two hyperbolic sectors instead of the elliptic ones, the index of $O_2$ would be zero.

We recall that by an analogous application of the index theory in the corresponding cases, it can be concluded that elliptic sectors appearing in the local phase portraits (L8), (L9), (L11), (L22), (L30), (L33), (L43), (L46) and (L47) of $O_1$, are indeed elliptic rather than hyperbolic.

In this case 1.1 there is only one possible phase portrait on the Poincaré disc, the one given in Figure 16 (G1).

**Case 1.6.** In this case $O_1$ has the local phase portrait (L3) and $O_2$ is a stable node. From the local results we can obtain three possible global phase portraits given in Figure 8.

![Subcase 1](image1.png) ![Subcase 2](image2.png) ![Subcase 3](image3.png)

**Figure 8.** Possible global phase portraits in case 1.6.

By Theorem 1.8 on the straight lines $z = z_0 \neq 0$ cannot be more than one contact point, but as it is shown in Figure 9 if subcases 1 and 2 are feasible, there exist straight lines $z = z_0$, with $-(R_c + c_3)/(2c_2) < z_0 < (R_c - c_3)/(2c_2)$, on which there exist two contact points, so we deduce that the only possible global phase portrait is the subcase 3, i.e. (G10) of Figure 16.

**Case 1.10.** In this case $O_1$ has the local phase portrait (L6) and $O_2$ is an unstable node. From the local results we can obtain three possible global phase portraits, but in two of them shown in Figure 10 we can find straight lines $z = z_0 \neq 0$ with $(R_c - c_3)/(2c_2) < z_0 < -(R_c + c_3)/(2c_2)$, on which there are two contact points,
so according to Theorem 4.8 they are not possible. Then the only possibility is the phase portrait (G20) of Figure 16.

**Case 2.2.** In this case $O_1$ has the local phase portrait (L47) and $O_2$ is an unstable node. From the local results and by Theorem 4.3 the phase portrait is symmetric, we obtain three possible global phase portraits, the ones given of Figure 11.

**Figure 11.** Possible global phase portraits in case (2.2).

By Theorem 4.8 we know that, under the conditions of this case, two invariant straight lines $z = \pm (R_c - c_3)/(2c_2)$ must exist, and it is only possible in the subcase 1, which provides the phase portrait (G42) of Figure 16.

**Case 2.6.** Here we distinguish three subcases and, in two of them, three global phase portraits appear, but in each case we use different arguments to prove which of the options is realizable. If $\mu = 0$, then $O_1$ has the local phase portrait (L5) and
$O_2$ is a stable node. We obtain three phase portraits, but we conclude that two of them are not feasible because we can find straight lines $z = z_0 \neq 0$ with two contact points, as it is shown in Figure 12. Therefore there is only one global phase portrait, the (G50) of Figure 16.

![Figure 12](image1.png)

**Figure 12.** Straight lines with two contact points on two subcases.

If $c_1 = 0$ and $\mu > -1$, then $O_1$ has the local phase portrait (L38) and $O_2$ is a stable node. We obtain three possible global phase portraits, the ones given in Figure 13. By Theorem 4.8 we know that, under the conditions of this case, two invariant straight lines $z = \pm (R_c - c_3)/(2c_2)$ must exist, and it is only possible in the subcase 3, which provides the phase portrait (G51) of Figure 16.

![Figure 13](image2.png)

**Figure 13.** Possible global phase portraits in case 2.6 with $c_1 = 0$ and $\mu > -1$.

If $c_1 = 0$ and $\mu < -1$, then $O_1$ has the local phase portrait (L41) and $O_2$ is a saddle. In this case we obtain only one phase portrait (G52) of Figure 16.

**Case 3.2.** Here we distinguish three subcases and in two of them there is only one possible global phase portait. More precisely, if $\mu < -1$ then $O_1$ has the local phase portrait (L8), $O_2$ is a saddle and the global phase portrait is (G64). If $\mu \in (-1, 0)$ then $O_1$ has the local phase portrait (L13), $O_2$ is an unstable node and we obtain the phase portrait (G65).

If $\mu > 0$ then $O_1$ has the local phase portrait (L6) and $O_2$ is an unstable node, but in this case we obtain three phase portraits, the ones given in Figure 14. By Theorem 4.8 there must exist a contact point on each straight line $z = z_0$, but if in subcases 1 and 2 we take a straight line $z = z_0$ with $z_0 > -c_3/(2c_2)$, there are not contact points on it, so there are not feasible. The only possibility is the subcase 3, which provides the phase portrait (G63) of Figure 16.
Case 4.2. Here we distinguish five different subcases. First if $c_1 = 0$, $\mu < -1$ and $a_0 + c_0\mu > 0$, then $O_1$ has the local phase portrait (L31) and $O_2$ is a saddle. In this case we obtain the global phase portrait (G90).

If $c_1 = 0$, $\mu < -1$ and $a_0 + c_0\mu < 0$, then $O_1$ has the local phase portrait (L32) and $O_2$ is a saddle. By Corollary 4.3 the phase portrait must be symmetric so we obtain three possibilities, given in Figure 15. We further know that there must exist an invariant straight line $z = -c_3/2c_2$, so we can deduce that subcase 2 is not feasible because that invariant straight line does not exist. As we also know that this invariant straight line is a separatrix in the local phase portrait of $O_1$, the one appearing in (L32), the subcase 3 is not feasible, because there would exist another separatrix over the invariant straight line that does not appear on (L32). So finally the only possible phase portrait is (G91).

The same happens in the next cases in which we initially obtain three possibilities but we can discard two of them with the same arguments, so finally we obtain the next results. If $\mu = 0$, then $O_1$ has the local phase portrait (L5) and $O_2$ is a stable node and we obtain the global phase portrait (G87). If $c_1 = 0$, $\mu > -1$ and $a_0 + c_0\mu > 0$, then $O_1$ has the local phase portrait (L27), $O_2$ is a stable node, and we obtain the phase portrait (G88). Finally if $c_1 = 0$, $\mu > -1$ and $a_0 + c_0\mu < 0$, then $O_1$ has the local phase portrait (L28), $O_2$ is a stable node, and the global phase portrait is (G89).

The same methods that we have used in the previous cases for determine which of the global phase portraits are realizable, must be used in some other cases, namely, 1.17, 1.18 with $\mu \geq -2$, 1.19, 2.7, 3.3, 3.4 with $\mu \geq -2$, 3.5 with $\mu > 0$, and finally 4.1 with $c_1 = 0$, $\mu > -1$ and $a_0 + c_0\mu < 0$. 

**Figure 14.** Possible global phase portraits in case 3.2 with $\mu > 0$. 

**Figure 15.** Possible global phase portraits in case 4.2 with $c_1 = 0$, $\mu < -1$ and $a_0 + c_0\mu < 0$. 

...
Remark 7.1. Global phase portraits (G43), (G48), (G57), (G84) and (G92) can appear both under condition $c_1 = 0$ or under $c_1 \neq 0$, so as we are interested in the topological classification we represent only the non-symmetric case respect to $z$-axis, but also the symmetric is possible. The same situation occurs with
the global phase portraits (G9), (G13)–(G16), (G18), (G19), (G23)–(G27), (G31)–(G36), (G41), (G45)–(G49), (G55), (G56), (G76)–(G83), (G92)–(G102), which can appear under the condition $c_3 = 0$ or $c_3 \neq 0$ so they can present the symmetric or the non-symmetric form respect to $x$-axis, altought we only represent one of them because we are only interested on the topological classification.
